Vitamin B$_{12}$ Deficiency
Sally P. Stabler, M.D.

A 57-year-old woman reports increasing symptoms of painful paresthesias in both legs for the past 18 months. Physical examination reveals impaired position sense and vibration sense. The serum vitamin B$_{12}$ level is 205 pg per milliliter (151.2 pmol per liter), which is above the lower end of the laboratory reference range. The hematocrit is 42%, with a mean corpuscular volume of 96 fl. The serum methylmalonic acid level is 3600 nmol per liter (normal level, <400), and the serum homocysteine level 49.1 μmol per liter (normal level, <14). How should this patient be further evaluated and treated?

The Clinical Problem

The recognition and treatment of vitamin B$_{12}$ deficiency is critical since it is a reversible cause of bone marrow failure and demyelinating nervous system disease. Vitamin B$_{12}$ (cobalamin) is synthesized by microorganisms and detected in trace amounts mostly in foods of animal origin. Uptake in the gastrointestinal tract depends on intrinsic factor, which is synthesized by the gastric parietal cells, and on the “cubam receptor” in the distal ileum. The most frequent cause of severe vitamin B$_{12}$ deficiency is a loss of intrinsic factor due to autoimmune atrophic gastritis, historically called “pernicious anemia,” even though many patients present with mainly neurologic manifestations.

Pathophysiology of Vitamin B$_{12}$ Deficiency

Vitamin B$_{12}$ is a cofactor for only two enzymes: methionine synthase and l-methylmalonyl–coenzyme A mutase (see Fig. 1 in the Supplementary Appendix, available with the full text of this article at NEJM.org). The interaction between folate and B$_{12}$ is responsible for the megaloblastic anemia seen in both vitamin deficiencies. Dyssynchrony between the maturation of cytoplasm and that of nuclei leads to macrocytosis, immature nuclei, and hypersegmentation in granulocytes in the peripheral blood (Fig. 1A). The hypercellular and dysplastic bone marrow can be mistaken for signs of acute leukemia (Fig. 1B). The ineffective erythropoiesis results in intramedullary hemolysis and release of lactate dehydrogenase, features that are similar to those of microangiopathic hemolytic anemia. Clinical and laboratory findings of megaloblastic anemia in the peripheral blood and bone marrow are shown in Figure 2.

Vitamin B$_{12}$ is necessary for the development and initial myelination of the central nervous system as well as for the maintenance of its normal function. Demyelination of the cervical and thoracic dorsal and lateral columns of the spinal cord, occasional demyelination of cranial and peripheral nerves, and demyelination of white matter in the brain (i.e., “combined-systems disease” or “subacute combined degeneration”) can occur with vitamin B$_{12}$ deficiency (Fig. 2). Pathologi-
cal analysis reveals a “spongy degeneration” due to the loss of and swelling of myelin sheaths; this degeneration is visible on magnetic resonance imaging. For unclear reasons, the severity of megaloblastic anemia is inversely correlated with the degree of neurologic dysfunction.

Less common conditions associated with vitamin B₁₂ deficiency include glossitis, malabsorption, infertility, and thrombosis (including thrombosis at unusual sites such as cerebral venous sinus thrombosis). Thrombosis has been attributed to the marked hyperhomocysteinemia seen in severe cases of vitamin B₁₂ deficiency. Patients occasionally have hyperpigmentation, which clears with treatment.

**CAUSES OF VITAMIN B₁₂ DEFICIENCY**

Table 1 and Figure 3 list causes of vitamin B₁₂ deficiency and recommended management. Pernicious anemia is discussed below, since this is the most common cause of severe vitamin B₁₂ deficiency worldwide.

Dietary vitamin B₁₂ deficiency in infants and children is also discussed because of the increasing recognition of severe abnormalities in exclusively breast-fed infants of mothers with vitamin B₁₂ deficiency.

**Pernicious Anemia**

Pernicious anemia is an autoimmune gastritis resulting from the destruction of gastric parietal cells and the associated lack of intrinsic factor to bind ingested vitamin B₁₂. The immune response is directed against the gastric H/K−ATPase, which accounts for associated achlorhydria. Other autoimmune disorders, especially thyroid disease, type 1 diabetes mellitus, and vitiligo, are also commonly associated with pernicious anemia. Whether the stomach pathogen *Helicobacter pylori* plays a causative role in pernicious anemia is unclear. Autoimmune gastritis may cause malabsorption of iron, with clinical iron deficiency developing early in life and eventually progressing to malabsorption of vitamin B₁₂. The prevalence of pernicious anemia ranges from 50 to 4000 cases per 100,000 persons, depending on the diagnostic criteria. All age groups are affected, but the median age range in large series is 70 to 80 years. Pernicious anemia is more common in persons of African or European ancestry (4.3% and 4.0% prevalence among older adults, respectively) than in those of Asian ancestry. Milder forms of atrophic gastritis with hypochlorhydria and an inability to release dietary protein-bound vitamin B₁₂ affect up to 20% of older adults.

**Dietary Deficiency in Infancy and Childhood**

The infant of a mother with vitamin B₁₂ deficiency may be born with the deficiency or it may occur if he or she is exclusively breast-fed, usually between 4 and 6 months of age. Typical manifestations of vitamin B₁₂ deficiency in children include failure of brain development and overall growth and development, developmental regression, hypotonia, feeding difficulties, lethargy, tremors, hyperirritability, and coma. Brain imaging may reveal atrophy and delayed myelination. Anemia may be present. Vitamin B₁₂ replacement results in rapid improvement in responsiveness, and many infants recover fully. However, the longer the period of deficiency, the more likely that there will be permanent disabilities. Mothers of infants with
Vitamin B₁₂ deficiency often have unrecognized pernicious anemia, but alternatively, they may have a history of gastric bypass surgery, the short-gut syndrome, or a long-term vegetarian or vegan diet.¹⁶ Tandem mass spectrometry, used in neonatal screening programs in all 50 states, may detect nutritional B₁₂ deficiency owing to an increase in propionyl carnitine, but direct measurement of methylmalonic acid has higher sensitivity.²⁵ Other causes of B₁₂ deficiency in children, such as ileal resections, the Imerslund–Gräsbeck syndrome, inflammatory bowel disease, and pernicious anemia, are listed in Table 1.¹⁸

**STRATEGIES AND EVIDENCE**

**EVALUATION**

Both the clinical recognition of vitamin B₁₂ deficiency and confirmation of the diagnosis by means of testing can be difficult. An approach to testing is shown in Table 2.

The patient's history may include symptoms of anemia, underlying disorders causing malabsorption, and neurologic symptoms. The most common neurologic symptoms are symmetric paresthesias or numbness and gait problems.⁴,⁵ The physical examination may reveal pallor, edema, pigmented changes in the skin, jaundice, or neurologic defects such as impaired vibration sense, impaired position and cutaneous sensation, ataxia, and weakness (Fig. 2).

Bone marrow biopsy and aspiration are not necessary for the diagnosis of megaloblastic anemia and may be misleading in cases of severe pancytopenia with hypercellularity, increased erythroblasts, and even cytogenetic abnormalities, confusing the diagnosis with acute leukemia.⁸–¹⁰ Imaging of the spinal cord is not indicated in patients with recognized vitamin B₁₂ deficiency, but in cases of severe myelopathy that are not initially recognized as the result of vitamin B₁₂ deficiency, there is characteristic hyperintensity on T₂-weighted imaging, described as an inverted V-shaped pattern in the cervical and thoracic spinal cord.¹¹

**Vitamin B₁₂ Assay**

The first test performed to confirm the diagnosis of vitamin B₁₂ deficiency is generally measurement of the serum vitamin B₁₂ level. Although an extremely low level (<100 pg per milliliter [<73.8 pmol per liter]) is usually associated with clinical deficiency, such low levels are infrequently observed. Both false negative and false positive values are common (occurring in up to 50% of tests) with the use of the laboratory-reported lower limit of the normal range as a cutoff point for deficiency.⁴,²⁴,²⁶ The high rate of false negative and false positive results may be
Abnormalities in infants and children
- Developmental delay or regression, permanent disability
- Does not smile
- Feeding difficulties
- Hypotonia, lethargy, coma
- Hyperirritability, convulsions, tremors, myoclonus
- Microcephaly
- Choreoathetoid movements

Optic atrophy, anosmia, loss of taste, glossitis

Infertility

Brain
- Altered mental status
- Cognitive defects
- “Megaloblastic madness”: depression, mania, irritability, paranoia, delusions, lability

Spinal cord
- Myelopathy
- Spongy degeneration
- Paresthesias
- Loss of proprioception: vibration, position, ataxic gait, limb weakness; spasticity (hyperreflexia); positive Romberg sign; Lhermitte’s sign; segmental cutaneous sensory level

Autonomic nervous system
- Postural hypotension
- Incontinence
- Impotence

Peripheral nervous system
- Cutaneous sensory loss
- Hyporeflexia
- Symmetric weakness
- Paresthesias

Peripheral blood
- Macrocytic red cells, macroovalocytes
- Anisocytosis, fragmented forms
- Hypersegmented neutrophils, 1% with six lobes or 5% with 5 lobes
- Leukopenia, possible immature white cells
- Thrombocytopenia
- Pancreatitis
- Elevated lactate dehydrogenase level (extremes possible)
- Elevated indirect bilirubin and aspartate aminotransferase levels
- Decreased haptoglobin level
- Elevated levels of methylmalonic acid, homocysteine, or both

Bone marrow
- Hypercellular, increased erythroid precursors
- Open, immature nuclear chromatin
- Dysynchrony between maturation of cytoplasm and nuclei
- Giant bands, metamyelocytes
- Karyorrhexis, dysplasia
- Abnormal results on flow cytometry and cytogenetic analysis

Bone/marrow
- Hypercellular, increased erythroid precursors
- Open, immature nuclear chromatin
- Dysynchrony between maturation of cytoplasm and nuclei
- Giant bands, metamyelocytes
- Karyorrhexis, dysplasia
- Abnormal results on flow cytometry and cytogenetic analysis

Spinal/cord
- Myelopathy
- Spongy degeneration
- Paresthesias
- Loss of proprioception: vibration, position, ataxic gait, limb weakness; spasticity (hyperreflexia); positive Romberg sign; Lhermitte’s sign; segmental cutaneous sensory level

Autonomic/nervous/system
- Postural hypotension
- Incontinence
- Impotence

Peripheral/nervous/system
- Cutaneous sensory loss
- Hyporeflexia
- Symmetric weakness
- Paresthesias

Peripheral/blood
- Macrocytic red cells, macroovalocytes
- Anisocytosis, fragmented forms
- Hypersegmented neutrophils, 1% with six lobes or 5% with 5 lobes
- Leukopenia, possible immature white cells
- Thrombocytopenia
- Pancytopenia
- Elevated lactate dehydrogenase level (extremes possible)
- Elevated indirect bilirubin and aspartate aminotransferase levels
- Decreased haptoglobin level
- Elevated levels of methylmalonic acid, homocysteine, or both
Figure 2 (facing page). Clinical and Laboratory Findings in Vitamin B₁₂ Deficiency.

The spectrum of disease associated with vitamin B₁₂ deficiency is wide, from asymptomatic to life-threatening pancytopenia or myelopathy. An increase in the mean red-cell volume or distribution width or a mean volume that is higher than expected for the patient’s age, presumed iron status (either high or low iron levels), and the presence of thalassemia are important determinants of macrocytosis, rather than an absolute value above the reference range. Cerebral symptoms are usually accompanied by paresthesias and signs of myelopathy or neuropathy.⁵

due to the fact that only 20% of the total measured vitamin B₁₂ is on the cellular delivery protein, transcobalamin; the remainder is bound to haptocorrin, a protein of unknown function.²⁷ Most laboratories now perform automated assays of vitamin B₁₂ on platforms used for many other analytes. There is often poor agreement when samples are assayed by different laboratories or with the use of different methods.³¹-³⁴ Because intrinsic factor is used as the assay-binding protein, anti–intrinsic factor antibodies (which are common in pernicious anemia) must be removed chemically from the sample, which has proved to be problematic in the automated assays.³⁵,³⁴ Recent studies show normal values³⁴ or falsely high values³³ of vitamin B₁₂ in many patients with pernicious anemia. New assays of holotranscobalamin (to measure the vitamin B₁₂ saturation of transcobalamin) provide a modest improvement in specificity over that provided by assays of total serum vitamin B₁₂, but they have not been clinically validated²⁷-²⁹ and are not yet available commercially in the United States.

Given the limitations of available assays, clinicians should not use a laboratory’s reported lower limit of the normal range to rule out the diagnosis of vitamin B₁₂ deficiency in patients with compatible clinical abnormalities. Clinicians should also recognize that vitamin B₁₂ values are frequently low in patients without other metabolic or clinical evidence of vitamin B₁₂ deficiency (i.e., megaloblastic anemia or myelopathy).

Measurement of Serum Methylmalonic Acid and Total Homocysteine

Measurement of methylmalonic acid, total homocysteine, or both is useful in making the diagnosis of vitamin B₁₂ deficiency in patients who have not received treatment.⁴,²²,²⁴,²⁶,³³,³⁵,³⁶ The levels of both methylmalonic acid and total homocysteine are markedly elevated in the vast majority (>98%) of patients with clinical B₁₂ deficiency (Fig. 4),²² including those who have only neurologic manifestations of deficiency (i.e., no anemia).⁴,²² Elevated levels of methylmalonic acid and total homocysteine decrease immediately after treatment, and the levels can be remeasured to document adequate vitamin B₁₂ replacement. Levels of these metabolites are normal in up to 50% of patients with low vitamin B₁₂ levels who have no hematologic or neurologic response to replacement therapy, indicating that the low values are false positive results.²⁹ Given the limitations of vitamin B₁₂ assays in confirming the diagnosis of B₁₂ deficiency,³¹,³⁴ it may be prudent to measure methylmalonic acid, total homocysteine, or both in patients with compatible clinical findings or provide empirical treatment with the use of defined end points to document a clinical response.

An elevated level of methylmalonic acid is reasonably specific for vitamin B₁₂ deficiency, and the level always decreases with vitamin B₁₂ therapy.²⁴,³⁶ Modest increases (to 300 to 700 nmol per liter) occur with renal failure.³⁶,³⁷ However, nearly all patients with megaloblastic anemia or myelopathy have levels of methylmalonic acid that are higher than 500 nmol per liter, and 86% have levels that are higher than 1000 nmol per liter (Fig. 3). The level of serum total homocysteine is less specific, since it is also elevated in folate deficiency,²²,³⁵ classic homocystinuria, and renal failure.

Tests to Determine the Cause of Vitamin B₁₂ Deficiency

If the patient consumes sufficient amounts of vitamin B₁₂ and has clinically confirmed B₁₂ deficiency, then malabsorption must be present. Testing for pernicious anemia is described in Table 2. A positive test for anti–intrinsic factor factor or anti–parietal-cell antibodies is indicative of pernicious anemia; surveillance for autoimmune thyroid disease is reasonable in patients with positive antibody tests. Chronic atrophic gastritis can be diagnosed on the basis of an elevated fasting serum gastrin level and a low level of serum pepsinogen I.³,¹⁰ Some experts recommend endoscopy to confirm gastritis and rule out gastric carcinoid and other gastric cancers, since patients with pernicious anemia are at increased risk for such cancers.³ The Schilling test of radioactive vitamin B₁₂

absorption is no longer available. A potential replacement absorption test is under development wherein the increase in vitamin B$_{12}$ saturation of holotranscobalamin is measured after several days of oral B$_{12}$ loading, but this requires further study.

### Treatment of Vitamin B$_{12}$ Deficiency

The daily requirement of vitamin B$_{12}$ has been set at 2.4 μg, but higher amounts — 4 to 7 μg per day — which are common in persons who eat meat or take a daily multivitamin, are associated with lower methylmalonic acid values.

Healthy older adults should consider taking supplemental crystalline vitamin B$_{12}$ as recommended by the Food and Nutrition Board. However, most patients with clinical vitamin B$_{12}$ deficiency have malabsorption and will require parenteral or high-dose oral replacement. Adequate supplementation results in resolution of megaloblastic anemia and resolution of or improvement in myelopathy.

#### Injected Vitamin B$_{12}$

There are many recommended schedules for injections of vitamin B$_{12}$ (called cyanocobalamin in the United States and hydroxocobalamin in Europe). About 10% of the injected dose (100 of 1000 μg) is retained. Patients with severe abnormalities should receive injections of 1000 μg at least several times per week for 1 to 2 weeks, then weekly until clear improvement is shown, followed by monthly injections. Hematologic response is rapid, with an increase in the reticulocyte count in 1 week and correction of megaloblastic anemia in 6 to 8 weeks. Patients with severe anemia and cardiac symptoms should be treated with transfusion and diuretic agents, and electrolytes should be monitored. Neurologic symptoms may worsen transiently and then subside over weeks to months. The severity and duration of the neurologic abnormalities before treatment influence the eventual degree of recovery. Treatment of pernicious anemia is lifelong. In patients in whom vitamin B$_{12}$ supplementation is discontinued after clinical recovery, neurologic symptoms recur within as short a period as 6 months, and megaloblastic anemia recurs in several years.

#### High-Dose Oral Treatment

High-dose oral treatment is effective and is increasingly popular. A study performed 45 years ago
Figure 3. The Normal Mechanisms and Defects of Absorption of Vitamin B\textsubscript{12}.

The vitamin B\textsubscript{12} (Cbl) released from food protein by peptic action is bound to haptocorrin (HC) in the stomach and travels to the duodenum, where pancreatic proteases digest the HC, releasing Cbl to bind to intrinsic factor (IF). The IF-Cbl complex binds to a specific receptor in the distal ileum (the cubam receptor) and is internalized, eventually released from lysosomes, and transported into the blood. Both HC and transcobalamin (TC) bind Cbl in the circulation, although the latter is the cellular delivery protein. Adapted from Stabler.\textsuperscript{6}

* To convert the values for vitamin B<sub>12</sub> to picomoles per liter, multiply by 0.7378.
† Available assays are largely chemiluminescent microparticle immunoassays performed with the use of automated analyzers that in general show higher values than the radiodilution and microbiologic assays used in past studies of clinically confirmed deficiency. Thus, these tests are likely to have lower sensitivities and specificities than the older assays.
‡ The holotranscobalamin assay has been studied widely in Europe but is not yet commercially available in the United States. The appropriate lower end of the reference range is still under debate. The values for sensitivity and specificity are reviewed in Heil et al.
§ Urinary methylmalonic acid has not been extensively studied, but values greater than 2.5 µmol per millimole of creatinine suggest deficiency.
¶ Elevated levels of methylmalonic acid fall with vitamin B<sub>12</sub> therapy, but an associated clinical response is highly variable, depending largely on the presence of vitamin B<sub>12</sub>–related disease.
‖ Evidence of a causal pathologic process does not confirm coexisting B<sub>12</sub> deficiency, since underlying gastrointestinal disease may predate the deficiency by many years.
** The relationship between atrophic body gastritis (autoimmune gastritis) and infection with Helicobacter pylori is variable. Antral sparing is a type of atrophic body gastritis in which the cells in the antrum can produce high levels of gastrin.
†† There is malabsorption if clinically proven vitamin B<sub>12</sub> deficiency is present in a patient who eats meat, receives multivitamin therapy, or both.
with daily oral treatment (169 nmol per liter, vs. 265 nmol per liter with parenteral treatment) and vitamin B₁₂ levels were significantly higher (1005 pg per milliliter vs. 325 pg per milliliter [741.5 vs. 239.8 pmol per liter]). A more recent trial with a similar design involving a proprietary oral vitamin B₁₂ preparation also revealed significantly lower levels of methylmalonic acid in the oral-treatment group at the 3-month follow-up.³⁰ In a randomized trial comparing oral with intramuscular vitamin B₁₂ (1000-μg doses, daily for 10 days, then weekly for 4 weeks, and monthly thereafter), the two groups had similar improvements in hematologic abnormalities and vitamin B₁₂ levels at 90 days.⁴⁴ Case series of patients treated with oral vitamin B₁₂ have yielded variable results; elevated levels of methylmalonic acid, homocysteine, or both were reported in about half of patients with malabsorption who were treated with twice-weekly oral doses of 1000 μg,⁵⁴ whereas normal homocysteine levels were reported in patients treated with 1500 μg daily after gastrectomy.⁶⁰ Data are lacking from long-term studies to assess whether oral treatment is effective when doses are administered less frequently than daily. Studies involving older adults, many of whom had chronic atrophic gastritis, showed that 60% required large oral doses (>500 μg daily) to correct elevated levels of methylmalonic acid.⁴⁷,⁴⁸

Proponents of parenteral therapy state that compliance and monitoring are better in patients who receive this form of therapy because they have frequent contact with health care providers, whereas proponents of oral therapy maintain that compliance will be improved in patients who receive oral therapy because of convenience, comfort, and decreased expense. High-dose vitamin B₁₂ tablets (500 to 1500 μg) are available in the United States without a prescription. Self-administered injections are also easily taught, economical, and in my experience, effective. Patients should be informed of the pros and cons of oral versus parenteral therapy, and regardless of the form of treatment, those with pernicious anemia or malabsorption should be reminded of the need for lifelong replacement.

**Areas of Uncertainty**

Vitamin B₁₂ deficiency is the major cause of hyperhomocysteinemia in countries with folate-fortified food, such as the United States and showed that 0.5 to 4% of radioactively labeled oral vitamin B₁₂ can be absorbed by passive diffusion in both normal controls and patients with pernicious anemia.⁴³ Thus, oral doses of 1000 μg deliver 5 to 40 μg, even if taken with food.

A randomized trial that compared an oral dose of 2000 μg daily with parenteral therapy (seven injections of 1000 μg of cyanocobalamin over a period of 1 month, followed by monthly injections) in patients with pernicious anemia, atrophic gastritis, or a history of ileal resection showed similar reductions in the mean corpuscular volume and increases in the hematocrit at 4 months in both groups.⁴⁸ All participants (four in each group) with paresthesias, ataxia, or memory loss had resolution or improved with treatment. However, levels of methylmalonic acid after treatment were significantly lower
Canada. Epidemiologic studies show significant associations between elevated homocysteine levels and vascular disease and thrombosis. However, large randomized trials of combined high-dose vitamin B therapy in patients with vascular disease have shown no reduction in vascular events. Vitamin $B_{12}$ status should be evaluated in patients with hyperhomocysteinemia before folate acid treatment is initiated.

The potential role of mild vitamin $B_{12}$ deficiency in cognitive decline with aging remains uncertain. Epidemiologic studies indicate an inverse association between vitamin $B_{12}$ supplementation and neurodegenerative disease, but results of randomized trials have been largely negative.

Besides oral tablets, vitamin B is available in sublingual preparations, oral sprays, nasal gels or sprays, and transdermal patches. Data on the absorption and efficacy of these alternative preparations are lacking.

**Guidelines**

Nutritional guidelines for vitamin $B_{12}$ intake are published by the Food and Nutrition Board, and nutritional guidelines for vegetarians are published by the American Dietetic Association. There are no recommendations from the American Society of Hematology for the diagnosis and treatment of vitamin $B_{12}$ deficiency. The American Academy of Neurology recommends measurements of vitamin $B_{12}$, methylmalonic acid, and homocysteine in patients with symmetric polyneuropathy. The American Society for Gastrointestinal Endoscopy recommends a single endoscopic evaluation at the diagnosis of pernicious anemia.

**Conclusions and Recommendations**

The patient in the vignette has neurologic abnormalities that are consistent with vitamin $B_{12}$ deficiency. Since vitamin $B_{12}$ levels may be above the lower end of the laboratory reference range even in patients with clinical deficiency, methylmalonic acid, total homocysteine, or both should be measured to document vitamin $B_{12}$ deficiency before treatment is initiated; the elevated levels in this patient confirm the diagnosis. In the absence of dietary restriction or a known cause of malabsorption, further evaluation is warranted—in particular, testing for pernicious anemia (anti-intrinsic factor antibodies). Either parenteral vitamin $B_{12}$ treatment (8 to 10 loading injections of 1000 μg each, followed by monthly 1000-μg injections), or high-dose oral vitamin $B_{12}$ treatment (1000 to 2000 μg daily) is an effective therapy. I would review both options (including the possibility of self-injection at home) with the patient. Effective vitamin replacement will correct blood counts in 2 months and correct or improve neurologic signs and symptoms within 6 months.

Dr. Stabler reports holding patents (assigned to the University of Colorado and Competitive Technologies) on the use of homocysteine, methylmalonic acid, and other metabolites in the diagnosis of vitamin $B_{12}$ and folate deficiency, but no longer receiving royalties for these patents. No other potential conflict of interest relevant to this article was reported.
